## Kits pour DOT-BLOT

### Qu'est ce qu'un Dot-Blot?

---

Un **Dot-Blot** est une technique utilisée pour détecter et identifier un ADN ciblé sur une membrane. Dans un point-blot, l'ADN cible à détecter n'est pas séparé par électrophorèse. Au lieu de cela, un mélange contenant l'ADN cible est appliqué directement sur une membrane en tant que point, puis est repéré directement à l'aide d'une sonde sur la membrane ou le substrat en papier. Cela est différent d'un transfert de Southern car les échantillons d'ADN ne sont pas séparés par électrophorèse. Ceci est ensuite suivi d'une détection à l'aide de sondes nucléotidiques.

La technique offre des économies considérables dans le temps par rapport à la chromatographie ou l'électrophorèse sur gel, car les procédures complexes de blot pour le gel ne sont pas nécessaires. Les taches de points peuvent confirmer la présence ou l'absence d'une biomolécule (ADN cible) qui peut être détectée par la sonde d'ADN.

Parce qu'un point-blot ne nécessite pas d'instruments complexes, les tests point-blot sont faciles à utiliser pour détecter la présence de microorganismes étrangers dans les tissus végétaux.

# Kits ELISA

## Qu'est ce qu'un ELISA?

---

ELISA (enzyme-linked immunosorbent assay) est une technique de dosage à base de plaques conçue pour détecter et quantifier des peptides, des protéines, des anticorps ou des hormones. Dans un ELISA, un antigène doit être immobilisé sur une surface solide puis complexé avec un anticorps lié à une enzyme. La détection s'effectue en évaluant l'activité enzymatique conjuguée par incubation avec un substrat, pour produire un produit mesurable. L'élément le plus crucial de la stratégie de détection est une interaction anticorps-antigène hautement spécifique.

Les ELISA sont généralement réalisés dans des plaques de polystyrène à 96 puits (ou 384 puits), qui se lient passivement aux anticorps et aux protéines. C'est cette liaison et l'immobilisation des réactifs qui rend les ELISA aussi faciles à concevoir et à réaliser. Le fait que les réactifs de l'ELISA immobilisés sur la surface de la microplaque permettent de séparer facilement le matériau lié à celui non lié pendant le dosage. Cette capacité à laver des matériaux non liés spécifiquement à la sécurité rend l'ELISA un outil puissant pour mesurer des analytes spécifiques dans une préparation brute.

# Immunofluorescence

## Qu'est ce que l'immunofluorescence?

---

L'immunofluorescence est basée sur l'utilisation d'anticorps spécifiques qui ont été chimiquement conjugués à des colorants fluorescents. Ces anticorps marqués se lient directement ou indirectement aux antigènes cellulaires.

La technique comporte un certain nombre d'applications biologiques différentes, y compris la détection des agents pathogènes des plantes. Le colorant fluorescent est excité à l'aide d'une lumière à haute énergie, qui est absorbée et émise à la lumière d'une longueur d'onde différente. La fluorescence émise peut être visualisée à l'aide d'une microscopie à fluorescence. La technique d'immunofluorescence permet une visualisation de la présence, ainsi que de la distribution des molécules cibles comme les agents pathogènes dans les échantillons de plantes.

Il existe deux classes de techniques d'immunofluorescence, primaire (ou direct) et secondaire (ou indirect). L'immunofluorescence secondaire ou indirecte utilise deux anticorps; Le premier (primaire) anticorps non lié se lie spécifiquement à la molécule cible, et l'anticorps secondaire, qui porte le fluorophore, reconnaît l'anticorps primaire et se lie à celui-ci. Les anticorps secondaires multiples peuvent lier un seul anticorps primaire. Ceci fournit une amplification du signal en augmentant le nombre de molécules de fluorophores par antigène. Ce protocole permet une plus grande flexibilité car une variété d'anticorps secondaires et de techniques de détection peuvent être utilisées pour un anticorps primaire donné.

# Kits de Lateral flow

## Qu'est ce Lateral flow?

Le flux latéral (Lateral flow) est basé sur l'utilisation de lits capillaires pour transporter du fluide le long d'une matrice contenant des antigènes. Si l'anticorps est capturé par l'antigène, il se produit une réaction colorimétrique. Cela fournit un résultat «oui» (positif) ou «non» (négatif).

## What is PCR?

La **PCR** ou **Polymerase chain reaction** est une technique utilisée dans la biologie moléculaire pour amplifier spécifiquement une seule copie ou quelques copies d'un segment spécifique d'ADN par plusieurs ordres de grandeur, générant des milliers à des millions de copies d'une séquence d'ADN particulière. C'est un moyen simple, peu coûteux et fiable de reproduire à plusieurs reprises un segment ciblé de l'ADN.

La PCR amplifie une région spécifique d'un brin d'ADN (la cible d'ADN). La plupart des méthodes de PCR amplifient des fragments d'ADN entre 0,1 et 10 kilo-base de paires (kbp), bien que certaines techniques permettent une amplification de fragments d'une taille allant jusqu'à 40 kbp. Cette technique est très spécifique, rapide et fiable pour la détection de pathogènes dans les échantillons de plantes.
